

Normalization :

Database Normalization is a technique of organizing the data in the database. It is a systematic approach of decomposing tables to eliminate redundancy. It is a multi-step process that puts data into tabular form, removing the duplicated data from its relational tables.

It is necessary to normalize the table that is present on the database. Every table in the database has to be in normal form. So, normalization is used for mainly two purposes:

1. It is used to eliminate repeated data. Having repeated data in the system not only makes the process slow but will cause trouble during the later part of transactions.
2. To ensure the data dependencies make some logical sense. Usually, the data is stored in database with certain logic. Huge datasets without any purposes are completely waste, it's like having an abundant resource without any application. The data that we have should make some logical sense.

Normalization came into existence because of the problems that occurred in the data. These problems are known as data anomalies. If a table is not properly normalized and has data redundancy, then it will not only eat up the extra memory space but will also make it difficult to handle and update the database.

Types of Normalization :

❖ 1st Normal form (1NF) :

In first normal form, the table should not be further divided. In simple terms, a single cell cannot hold multiple values. If a table contains a composite or multivalued attributes, it violates the first normal form. The functions performed in the first normal form are :

1. It removes repeating groups from the table.
2. It creates a separate table for each set of related data.
3. It identifies each set of related data with the primary key.

Example:

| Employee ID | Employee Name | Phone Number | Salary |
|-------------|---------------|----------------------------------|--------|
| 1EDU001 | Alex | +91 8553206126 +91 9449424949 | 60,131 |
| 1EDU002 | Barry | +91 8762989672 | 48,302 |
| 1EDU003 | Clair | +91 9916255225 | 22,900 |
| 1EDU004 | David | +91 6363625811 +91 8762055007 | 81,538 |

| Employee ID | Employee Name | Phone Number | Salary |
|-------------|---------------|----------------|--------|
| 1EDU001 | Alex | +91 8553206126 | 60,131 |
| 1EDU001 | Alex | +91 9449424949 | 60,131 |
| 1EDU002 | Barry | +91 8762989672 | 48,302 |
| 1EDU003 | Clair | +91 9916255225 | 22,900 |
| 1EDU004 | David | +91 6363625811 | 81,538 |
| 1EDU004 | David | +91 8762055007 | 81,538 |

❖ 2nd Normal Form (2NF) :

The first condition in the 2nd NF is that the table has to be in 1st NF. The second normal form is non key attribute depend on entire primary key. That mean the each column directly related to primary key column and not other column.

Example:

| Employee ID | Department ID | Office Location |
|-------------|---------------|-----------------|
| 1EDU001 | ED-T1 | Pune |
| 1EDU002 | ED-S2 | Bengaluru |
| 1EDU003 | ED-M1 | Delhi |
| 1EDU004 | ED-T3 | Mumbai |

This table has a composite primary key Employee ID, Department ID. The non-key attribute is Office Location. In this case, Office Location only depends on Department ID, which is only part of the primary key. Therefore, this table does not satisfy the second Normal Form.

To bring this table to Second Normal Form, we need to break the table into two parts. Which will give us the below tables:

| Employee ID | Department ID |
|-------------|---------------|
| 1EDU001 | ED-T1 |
| 1EDU002 | ED-S2 |
| 1EDU003 | ED-M1 |
| 1EDU004 | ED-T3 |

| Department ID | Office Location |
|---------------|-----------------|
| ED-T1 | Pune |
| ED-S2 | Bengaluru |
| ED-M1 | Delhi |
| ED-T3 | Mumbai |

As you can see we have removed the partial functional dependency that we initially had. Now, in the table, the column Office Location is fully dependent on the primary key of that table, which is Department ID.

❖ 3rd Normal Form (3NF) :

The same rule applies as before i.e, the table has to be in 2NF before proceeding to 3NF. The Third Normal Form (3NF) ensures that all columns in a table depend only on the primary key and not on any other non-key column in that table.

Example:

| Student ID | Student Name | Subject ID | Subject | Address |
|------------|--------------|------------|---------|-----------|
| 1DT15ENG01 | Alex | 15CS11 | SQL | Goa |
| 1DT15ENG02 | Barry | 15CS13 | JAVA | Bengaluru |
| 1DT15ENG03 | Clair | 15CS12 | C++ | Delhi |
| 1DT15ENG04 | David | 15CS13 | JAVA | Kochi |

In the above table, Student ID determines Subject ID, and Subject ID determines Subject. Therefore, Student ID determines Subject via Subject ID. This implies that we have a transitive functional dependency, and this structure does not satisfy the third normal form.

Now in order to achieve third normal form, we need to divide the table as shown below:

| Student ID | Student Name | Subject ID | Address |
|------------|--------------|------------|-----------|
| 1DT15ENG01 | Alex | 15CS11 | Goa |
| 1DT15ENG02 | Barry | 15CS13 | Bengaluru |
| 1DT15ENG03 | Clair | 15CS12 | Delhi |
| 1DT15ENG04 | David | 15CS13 | Kochi |

| Subject ID | Subject |
|------------|---------|
| 15CS11 | SQL |
| 15CS13 | JAVA |
| 15CS12 | C++ |
| 15CS13 | JAVA |

As you can see from the above tables all the non-key attributes are now fully functional dependent only on the primary key. In the first table, columns Student Name, Subject ID and Address are only dependent on Student ID. In the second table, Subject is only dependent on Subject ID.

❖ **Boyce Codd Normal Form (BCNF) :**

This is also known as 3.5 NF. It's the higher version 3NF where every determinant (a column that uniquely identifies another column) must be a candidate key, ensuring no redundancy due to functional dependencies.

Example:

| Student ID | Subject | Professor |
|------------|---------|--------------|
| 1DT15ENG01 | SQL | Prof. Mishra |
| 1DT15ENG02 | JAVA | Prof. Anand |
| 1DT15ENG02 | C++ | Prof. Kanthi |
| 1DT15ENG03 | JAVA | Prof. Anand |
| 1DT15ENG04 | DBMS | Prof. Lokesh |

In order to satisfy the BCNF, we will be dividing the table into two parts. One table will hold Student ID which already exists and newly created column Professor ID.

| Student ID | Professor ID |
|------------|--------------|
| 1DT15ENG01 | 1DTPF01 |
| 1DT15ENG02 | 1DTPF02 |
| 1DT15ENG02 | 1DTPF03 |
| : | : |

And in the second table, we will have the columns Professor ID, Professor and Subject.

| Professor ID | Professor | Subject |
|--------------|--------------|---------|
| 1DTPF01 | Prof. Mishra | SQL |
| 1DTPF02 | Prof. Anand | JAVA |
| 1DTPF03 | Prof. Kanthi | C++ |
| : | : | : |

By doing this we are satisfied the Boyce Codd Normal Form.

❖ **4th Normal Form (4NF) :**

The 4NF is the refinement of BCNF ensures that a table should not have multiple sets of related data within a single table. Each fact in a table should be dependent only on the primary key.

Example :

| Student ID | Subject ID | Subject |
|------------|------------|---------|
| 1DT15ENG01 | 15CS11 | SQL |
| 1DT15ENG02 | 15CS13 | JAVA |
| 1DT15ENG02 | 15CS12 | C++ |

After 4NF,

| Student ID | Subject ID |
|------------|------------|
| 1DT15ENG01 | 15CS11 |
| 1DT15ENG02 | 15CS13 |
| 1DT15ENG02 | 15CS12 |

| Student ID | Subject |
|------------|---------|
| 1DT15ENG01 | SQL |
| 1DT15ENG02 | JAVA |
| 1DT15ENG02 | C++ |
